

Matrix discrepancy and optimization

The Beck–Fiala discrepancy conjecture

Difficulty: extreme **Importance:** broadly interesting

Provenance: source-stated conjecture.

Status: no unrestricted resolution found in screening on 2026-09-08.

Does a finite universal constant $C > 0$ exist such that the following holds for every pair of positive integers m, n , every integer t with $1 \leq t \leq m$, and every matrix $A = (a_{ij}) \in \{0, 1\}^{m \times n}$? If

$$\sum_{i=1}^m a_{ij} \leq t \quad (1 \leq j \leq n),$$

then some signing $x \in \{-1, 1\}^n$ satisfies

$$\|Ax\|_{\infty} \leq C\sqrt{t}.$$

The constant must be independent of m, n, t . All columns are available when choosing the signing. The zero-sparsity case is trivial and excluded from the quantifiers.

The matrix is the incidence matrix of a set system: each element belongs to at most t sets, and the signing should balance every set. The problem asks whether column sparsity alone controls the simultaneous row error at its conjectured square-root scale. It is a special case of the Komlós conjecture after column normalization, but an independent classical source-stated conjecture for incidence matrices.

Status check — 2026-09-08

checked 2607.14238v1 (2026-07-15), 2508.03961v2 (2025-09-09), and searches “Beck Fiala conjecture solved 2026 logarithmic sparsity” and “Online Beck Fiala Down to Logarithmic Sparsity”. The 2026 work reaches sparsities $t \geq (\log n)^{1+o(1)}$ in its notation translated to n columns; it does not establish the assertion for all sparsities. Online lower bounds concern a more restrictive information model. No full resolution or withdrawal was found.
