

Matrix inequalities and norms

Chollet's permanent inequality for Hadamard products

Difficulty: extreme **Importance:** interesting to the community

Status: explicit conjecture; low-order proof claims do not settle the general case

For an $n \times n$ matrix $C = (c_{ij})$, define

$$\text{per } C = \sum_{\sigma \in S_n} \prod_{i=1}^n c_{i, \sigma(i)}.$$

Is it true that, for every integer $n \geq 1$ and every pair of complex Hermitian positive-semidefinite matrices $A, B \in \mathbb{C}^{n \times n}$,

$$\text{per}(A \circ B) \leq (\text{per } A)(\text{per } B), \quad (A \circ B)_{ij} = a_{ij}b_{ij}?$$

Relevance

The Hadamard product preserves positive semidefiniteness and corresponds to tensor products of Gram vectors. The conjecture seeks a computable structural upper bound for a difficult matrix polynomial under this basic matrix operation. It concerns matrix inequalities and permanent computation.

Status check — 2026-09-08

The August 2026 preprint claims the displayed inequality through order six. That claim has not been independently refereed here and does not claim the unrestricted result; the unresolved target includes orders $n \geq 7$. The April 2026 paper addresses structured classes. Searches for “Chollet conjecture”, “permanent”, “proof”, and 2025–2026 found no general resolution. Disproofs of the stronger Bapat–Sunder and permanent-on-top conjectures do not refute this statement.
