

Matrix discrepancy and optimization

The sharp Lovász-theta constant for dense random graphs

Difficulty: challenging **Importance:** broadly interesting

Status: Open

Rating rationale: A sharp expectation constant requires new random SDP analysis beyond order bounds; it connects matrix optimization with probabilistic combinatorics.

Let G_n be the simple random graph on n labelled vertices in which each unordered pair is an edge independently with probability $1/2$. For a graph G , define its Lovász number by

$$\vartheta(G) = \max\{\langle J, X \rangle : X \in \mathbb{R}^{n \times n}, X = X^T \succeq 0, \operatorname{tr} X = 1, X_{ij} = 0 \text{ for } \{i, j\} \in E(G)\},$$

where J is the all-ones matrix and $\langle J, X \rangle = \sum_{i,j} X_{ij}$.

Conjecture. $\lim_{n \rightarrow \infty} \mathbb{E} \vartheta(G_n) / \sqrt{n} = 1$.

This asks for the leading constant of a random semidefinite matrix optimization problem. It is an expectation statement; convergence in probability is not substituted for it.

Status check — 2026-09-10

The archived 2026 paper retains the conjecture. Targeted searches for the Lovász number of dense Erdős–Rényi graphs and a sharp leading constant through September 2026 found no resolution. The adjacent circulant problem uses a different random matrix ensemble and is recorded separately.

Audit update (2026-09-10): Rechecked the 2026 Conjecture 17 and searched for a sharp dense-random-graph theta constant. No resolution of the expectation limit was located. This is a bounded literature check, not a proof that no solution exists.
