

Matrix inequalities and norms

Freewan–Hayajneh inequality for sums of weighted geometric means

Difficulty: challenging **Importance:** interesting to the community

Status: Partially resolved

Rating rationale: The coupled power and weight parameters make extension beyond the proved cases challenging; positive definite aggregation and matrix-function estimates give community relevance.

Problem statement

For positive definite matrices, define

$$A\#_t B = A^{1/2}(A^{-1/2}BA^{-1/2})^t A^{1/2}.$$

Is the following true for all positive integers m, n , all $A_i, B_i \in \mathbb{C}^{n \times n}$ positive definite, all $t \in [0, 1]$, and all real $s, r, p > 0$ with $sr \geq 1$? Set $A = \sum_i A_i$, $B = \sum_i B_i$. For every unitarily invariant norm on $n \times n$ matrices, does

$$\left\| \sum_{i=1}^m (A_i^s \#_t B_i^s)^r \right\| \leq \left\| \left(A^{(1-t)srp/2} B^{tsrp} A^{(1-t)srp/2} \right)^{1/p} \right\|$$

hold? Here all real powers of positive definite matrices use spectral functional calculus, and unitary invariance means $\|UXV\| = \|X\|$ for unitary U, V .

The conjecture controls the norm of a sum of nonlinear positive definite matrix means using only sums of the input matrices. It is relevant to aggregation and interpolation of positive definite data and to estimates for algorithms involving matrix powers. The full weighted statement is one problem; its individual parameter cases are not separate entries.

Status check (2026-09-10): the current arXiv record lists v1, December 30, 2023. Its theorem treats $t = 1/2$, $s \geq 2$, $r \geq 1$, $p > 0$, $rp \geq 1$; the abstract explicitly identifies this as a partial answer to the weighted conjecture. The original publisher text and the later preprint statement were compared. Searches for both exact titles, the authors and “weighted geometric mean conjecture”, including 2025/2026, found no full proof or counterexample. Openness is subject to this search limit.
