

Matrix inequalities and norms

Lemos–Soares singular-value log-majorization

Difficulty: challenging **Importance:** interesting to the community**Status:** Open

Rating rationale: Controlling every partial product of singular values is challenging despite the proved eigenvalue-modulus analogue; the resulting norm comparisons are relevant across matrix analysis.

Problem statement

Let $A, B \in \mathbb{C}^{n \times n}$ be positive definite and $t \in [0, 1]$, and define $A \#_t B = A^{1/2}(A^{-1/2}BA^{-1/2})^t A^{1/2}$. Write $s_1(X) \geq \dots \geq s_n(X)$ for the singular values of X .

Does

$$\prod_{j=1}^k s_j(A^t(A \#_t B)B^{1-t}) \leq \prod_{j=1}^k s_j(AB), \quad 1 \leq k < n,$$

hold for every positive integer n , every such A, B, t , with equality of the products for $k = n$? This is the assertion $s(A^t(A \#_t B)B^{1-t}) <_{\log} s(AB)$. The positive semidefinite version in the sources is recovered by continuous regularization $A + \varepsilon I, B + \varepsilon I$; endpoints in t can be stated directly.

The question concerns the singular values of a product involving a matrix geometric mean. Such multiplicative bounds imply norm and determinant estimates useful in numerical treatment of positive definite matrices. An analogue for eigenvalue moduli has already been proved, but changes both sides of the comparison and does not answer this singular-value question.

Status check (2026-09-10): the original arXiv record lists v1. The July 14, 2026 paper reproduces precisely this inequality as (1.2) on p. 3 and explicitly says that it is still open. The publisher PDF was inaccessible, but the indexed primary-paper text in the public mirror exposed this passage and the later discussion distinguishing the new partial results. Searches for “Lemos Soares singular log-majorization conjecture”, the exact later title, and 2025/2026 found no subsequent announced full resolution. This is a bounded search, not certification of openness.
